Observation

Whole sea ice state

Data assimilation consists in optimally updating the whole sea ice state, given partial observations

1. Simple sea ice model

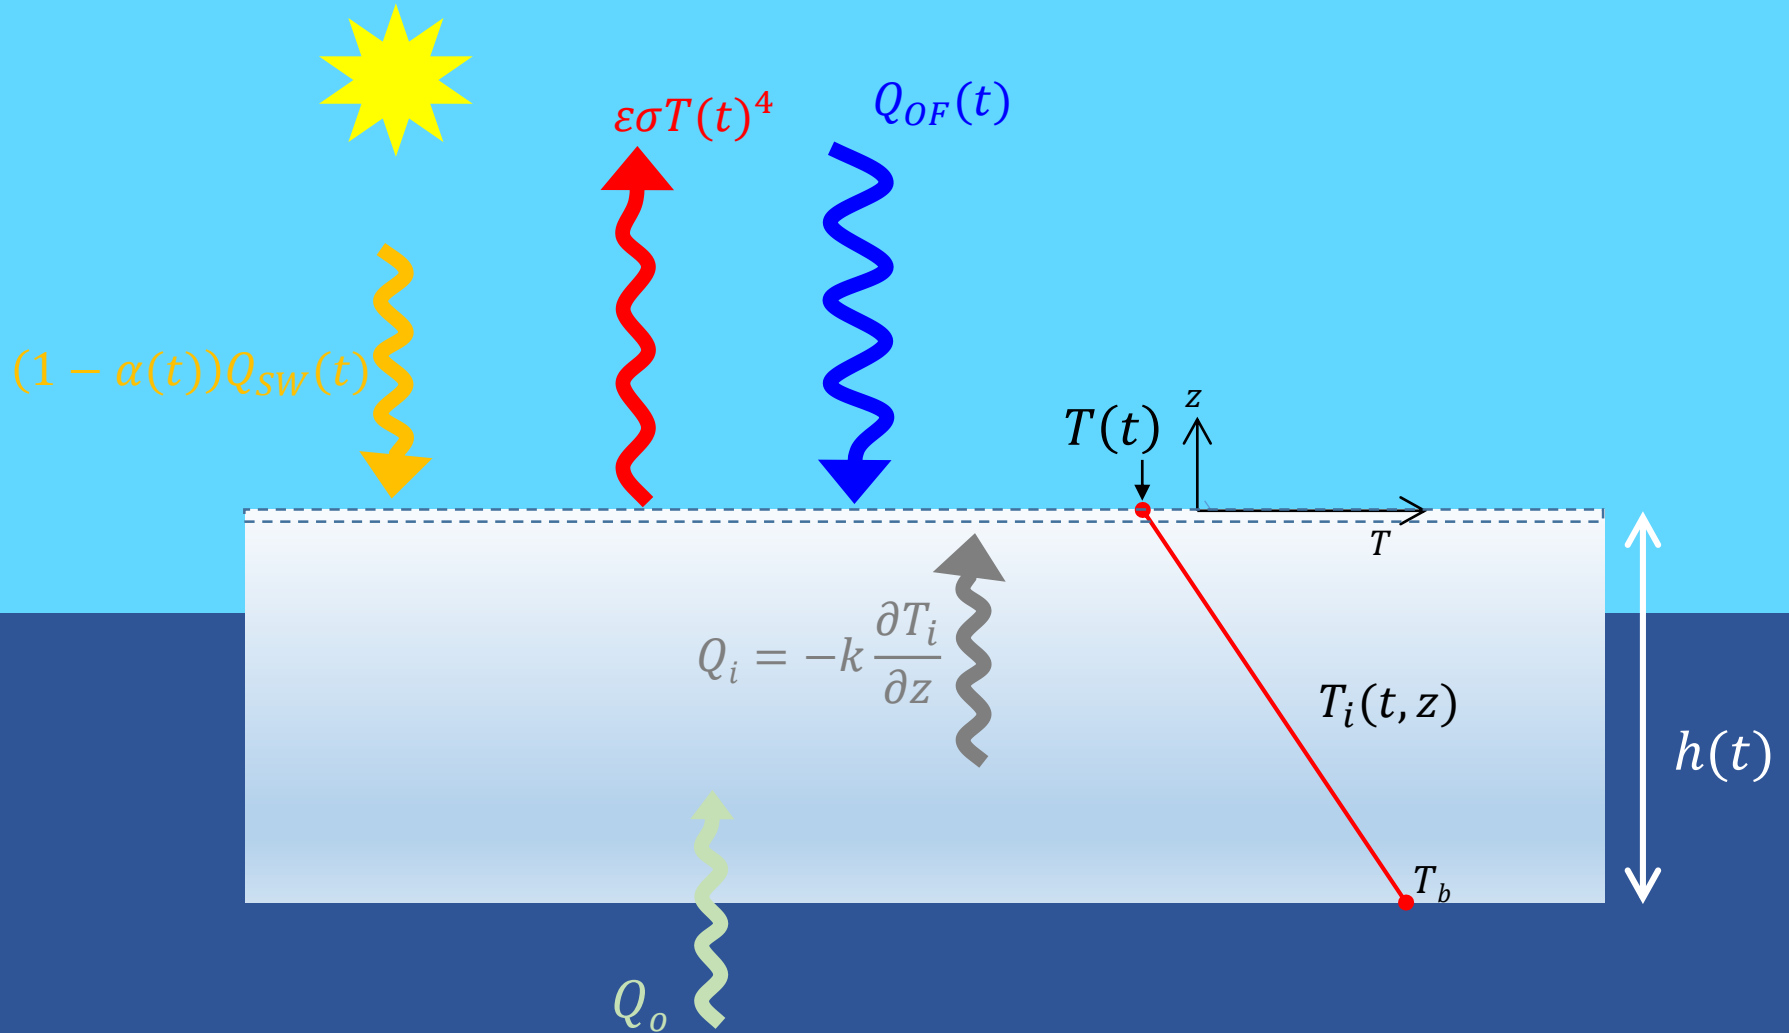

2. Comprehensive sea ice model

1. Simple sea ice model

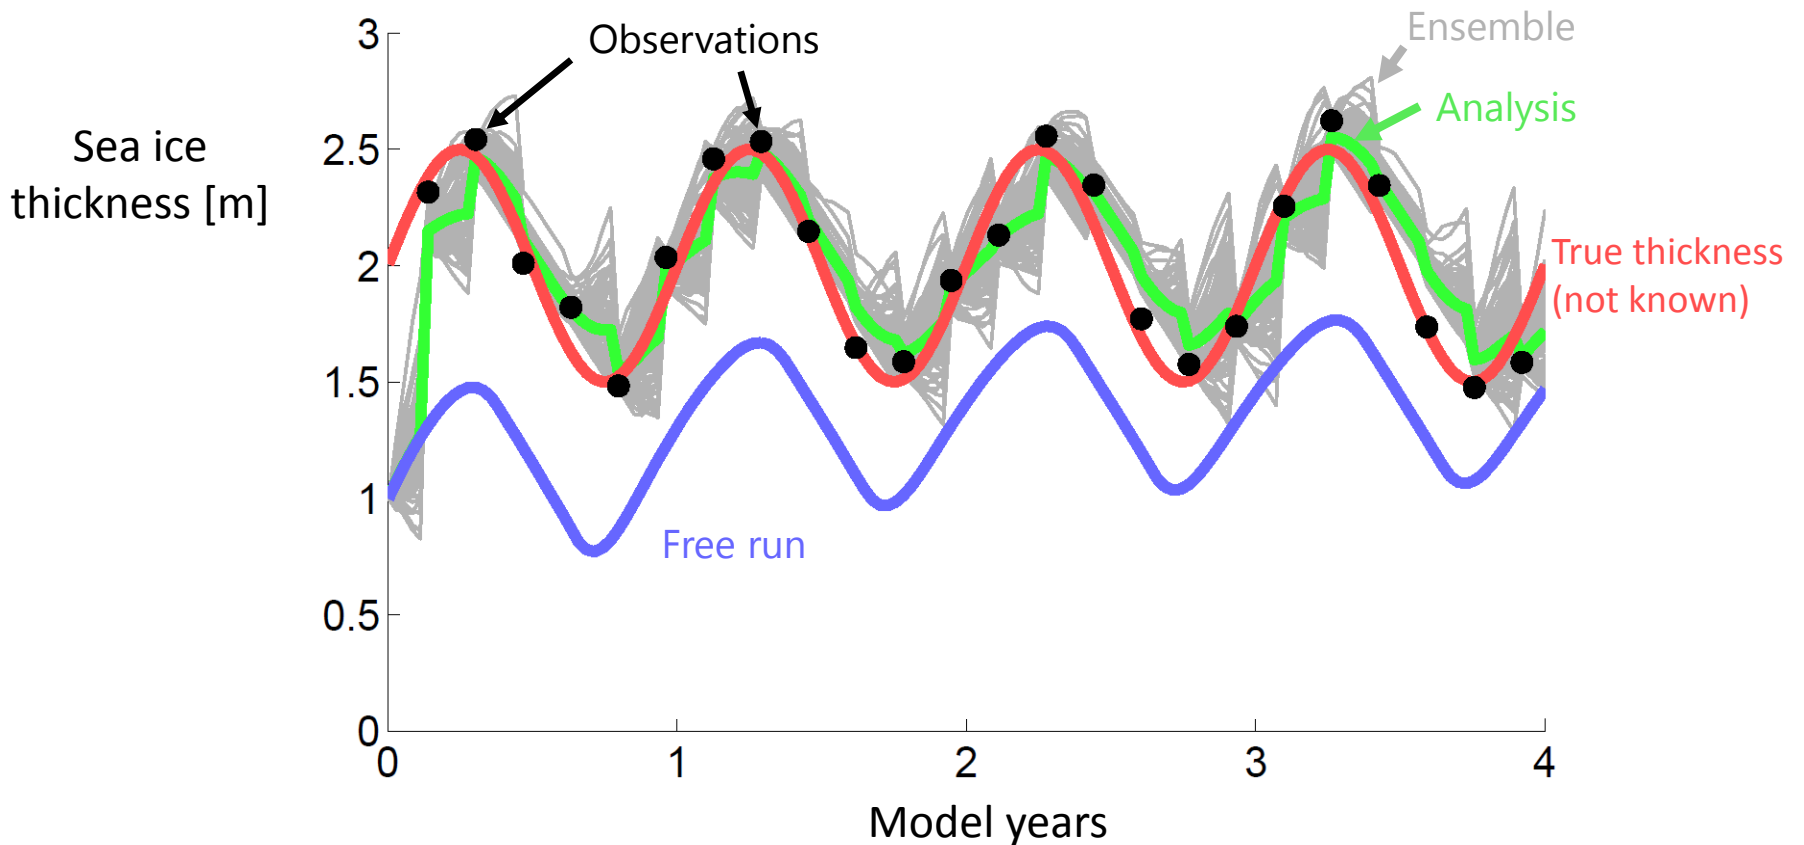

2. Comprehensive sea ice model

2-variable sea ice model

[Semtner, 1976; Notz, 2005]

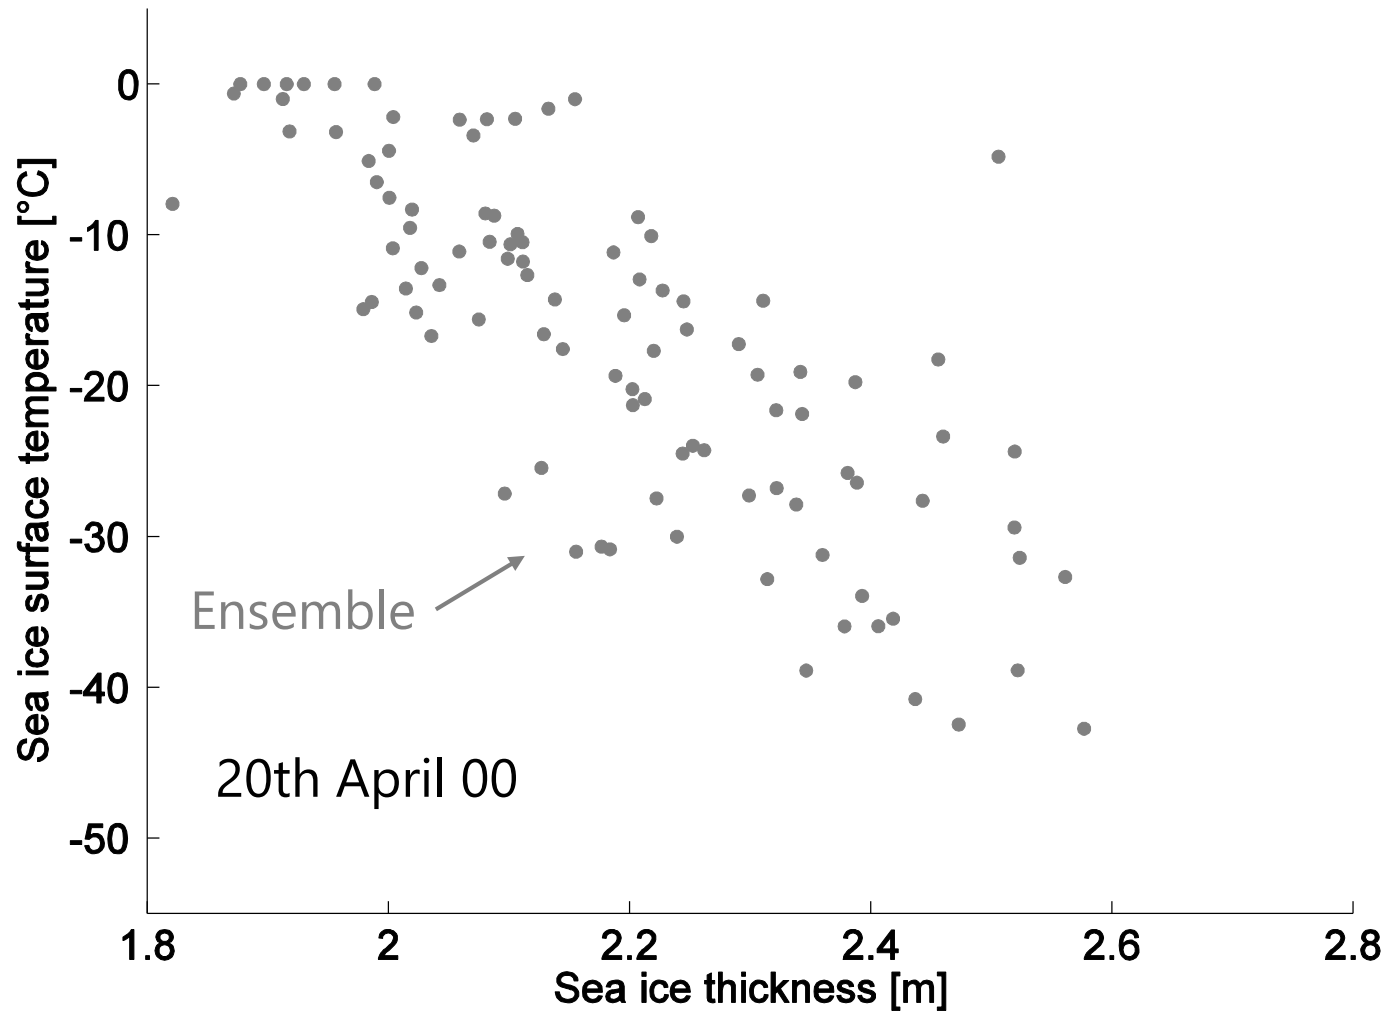

The easy part: updating the observed variable

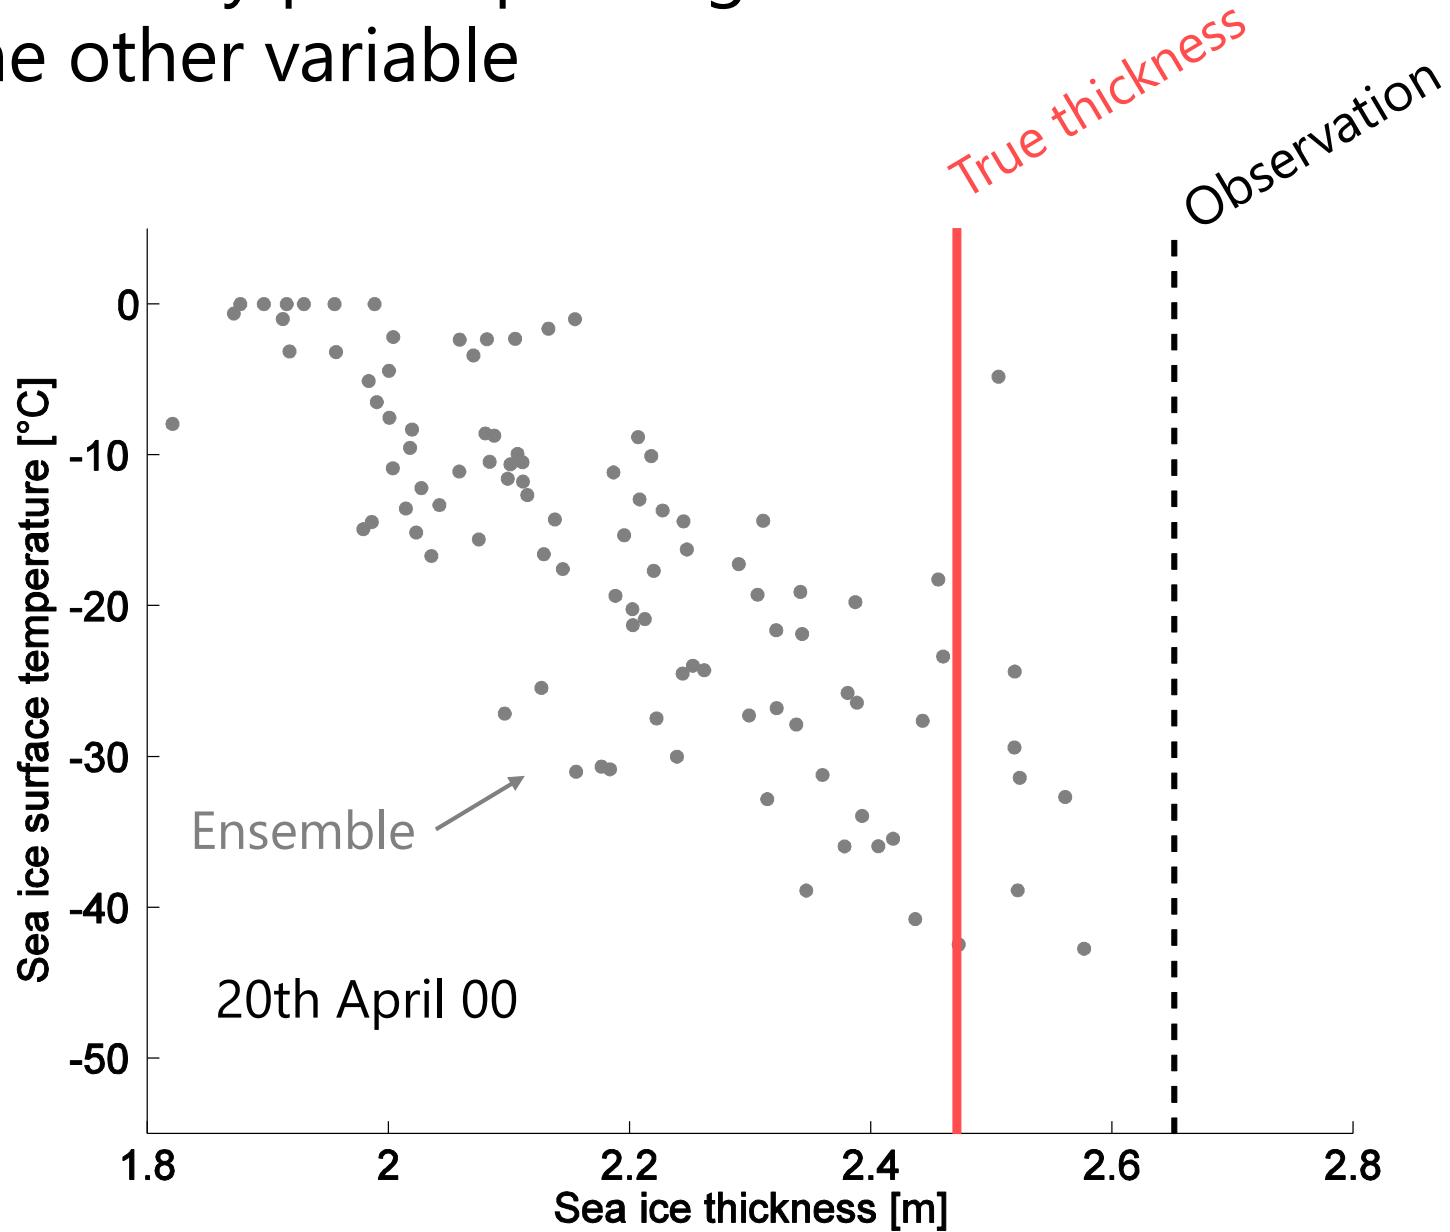

The easy part: updating the observed variable

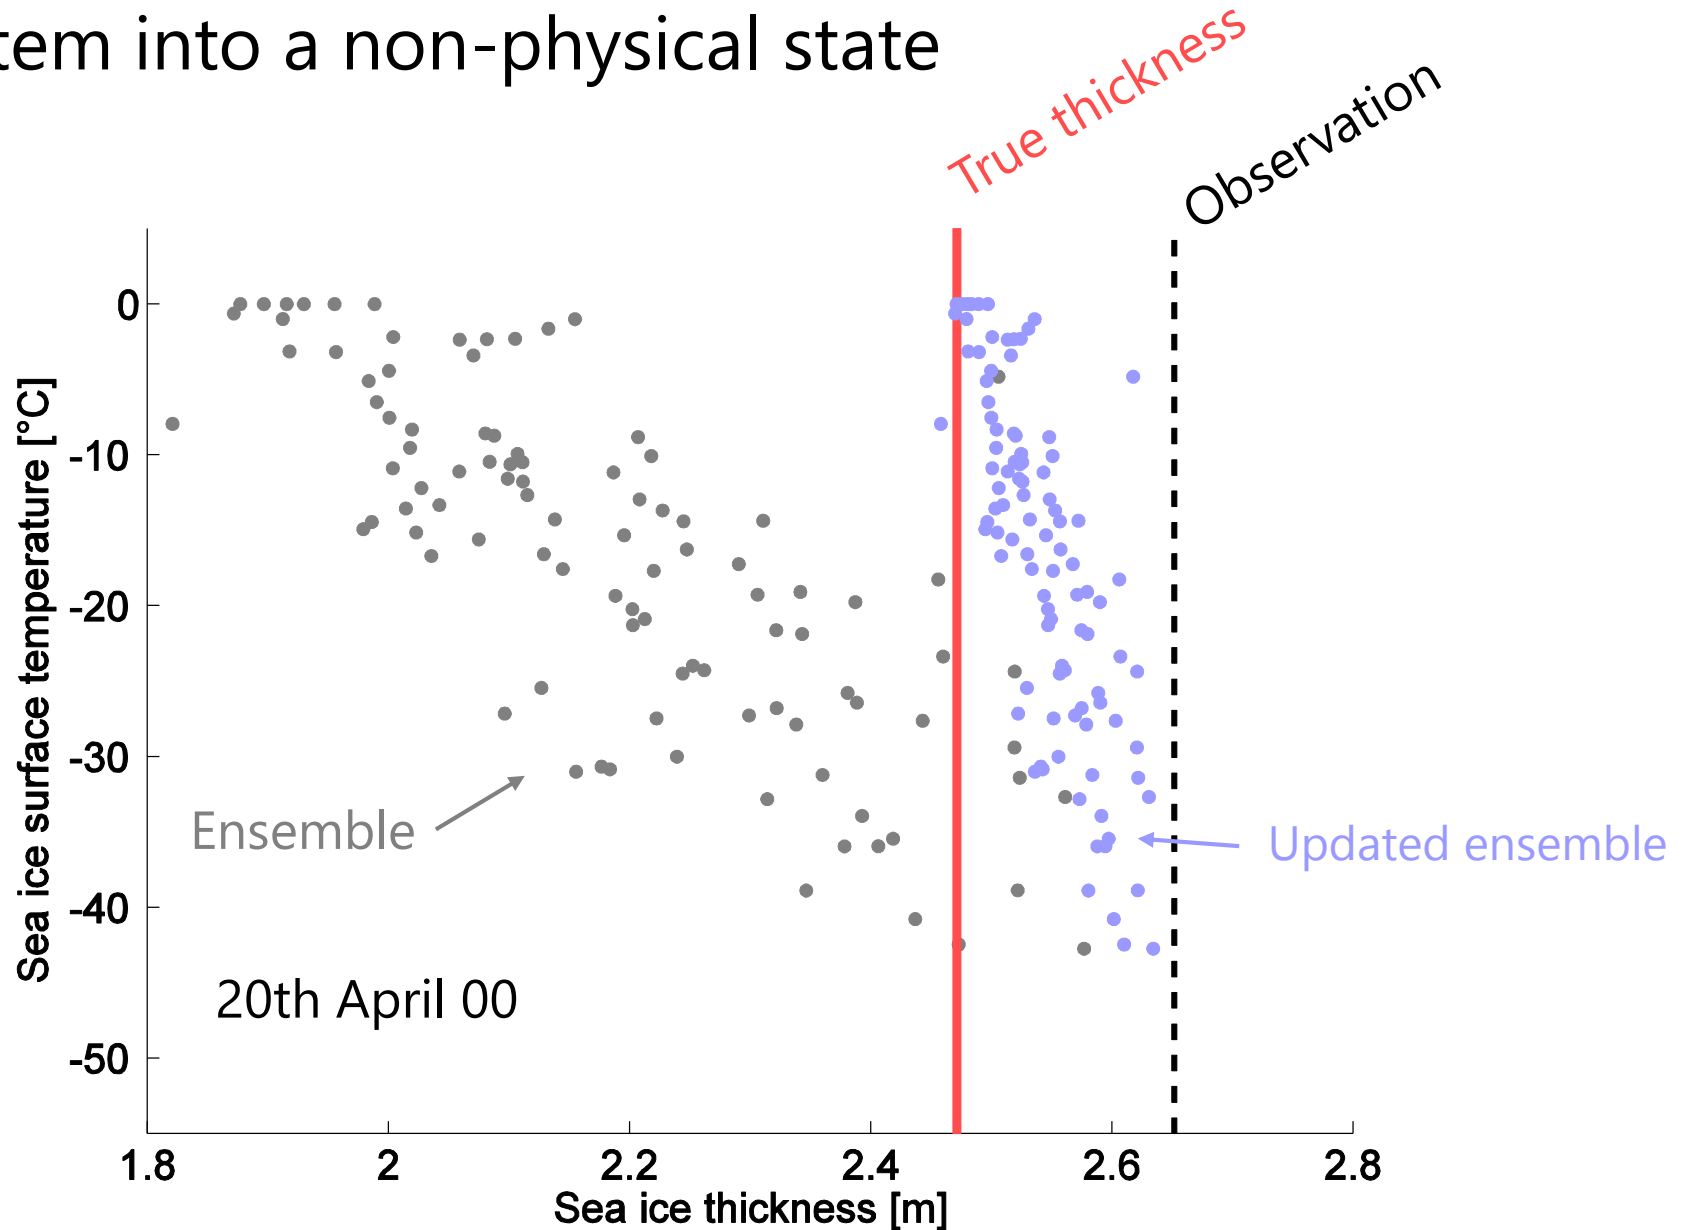

The tricky part: updating the other variable

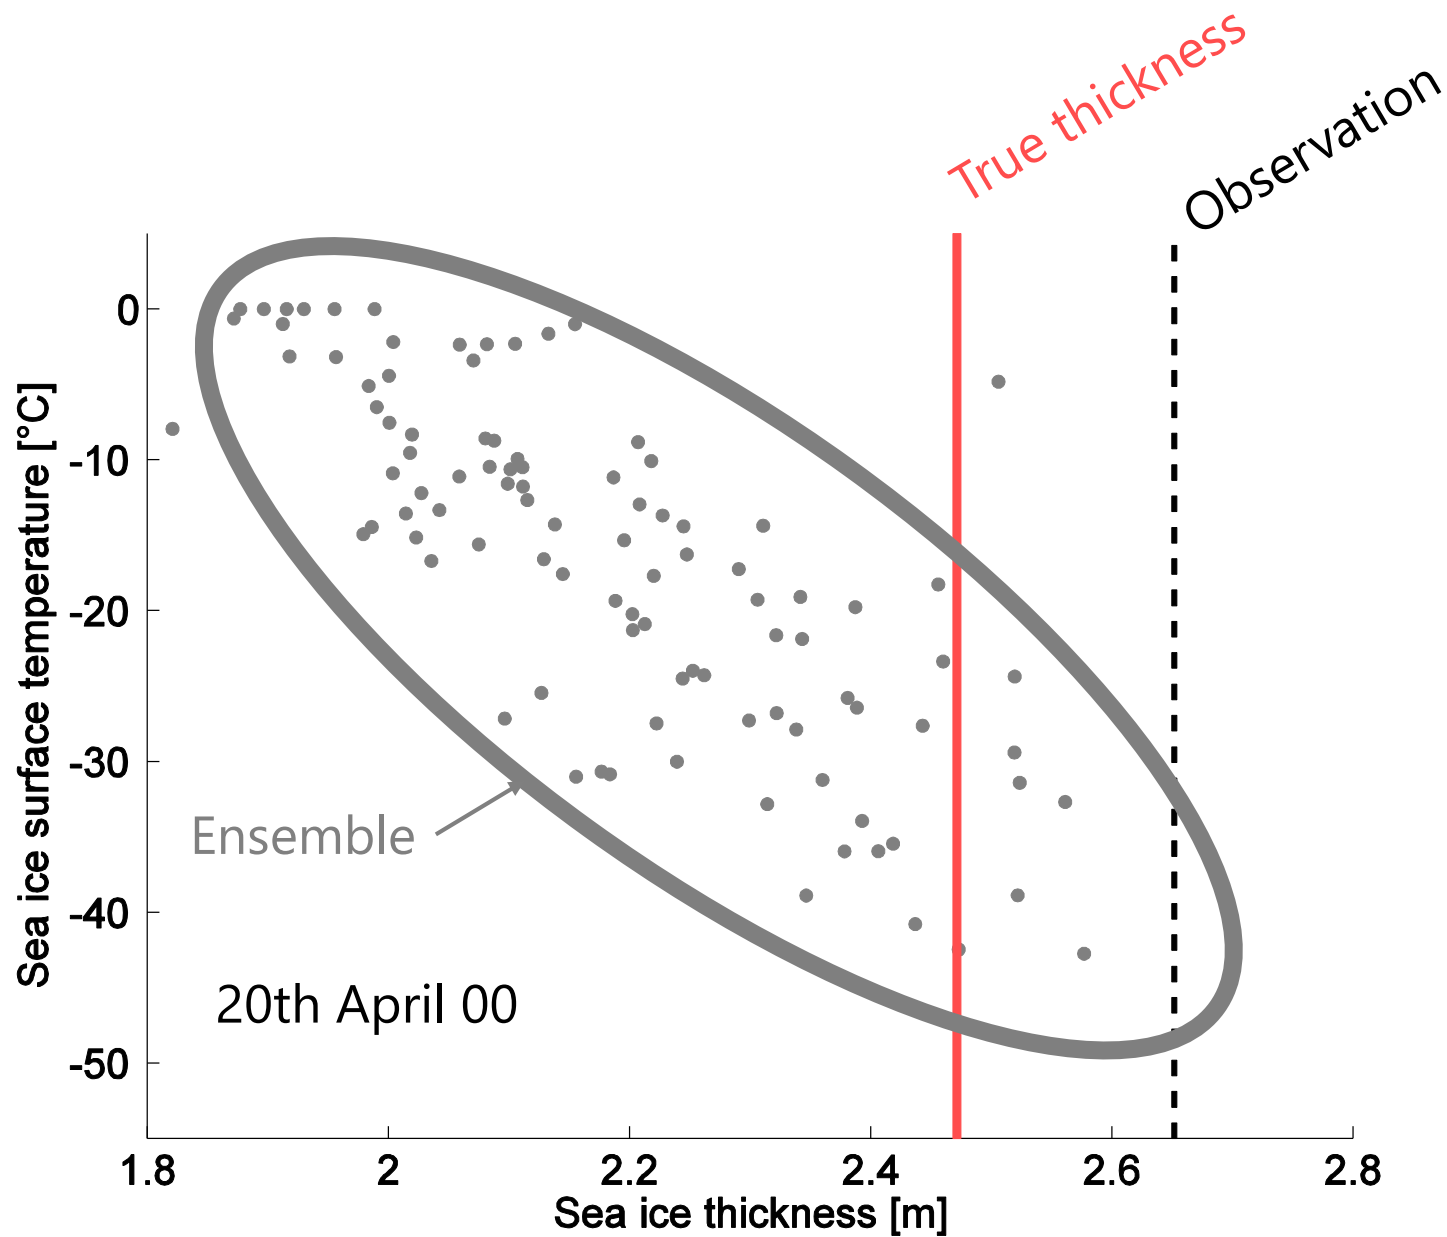

The tricky part: updating the other variable

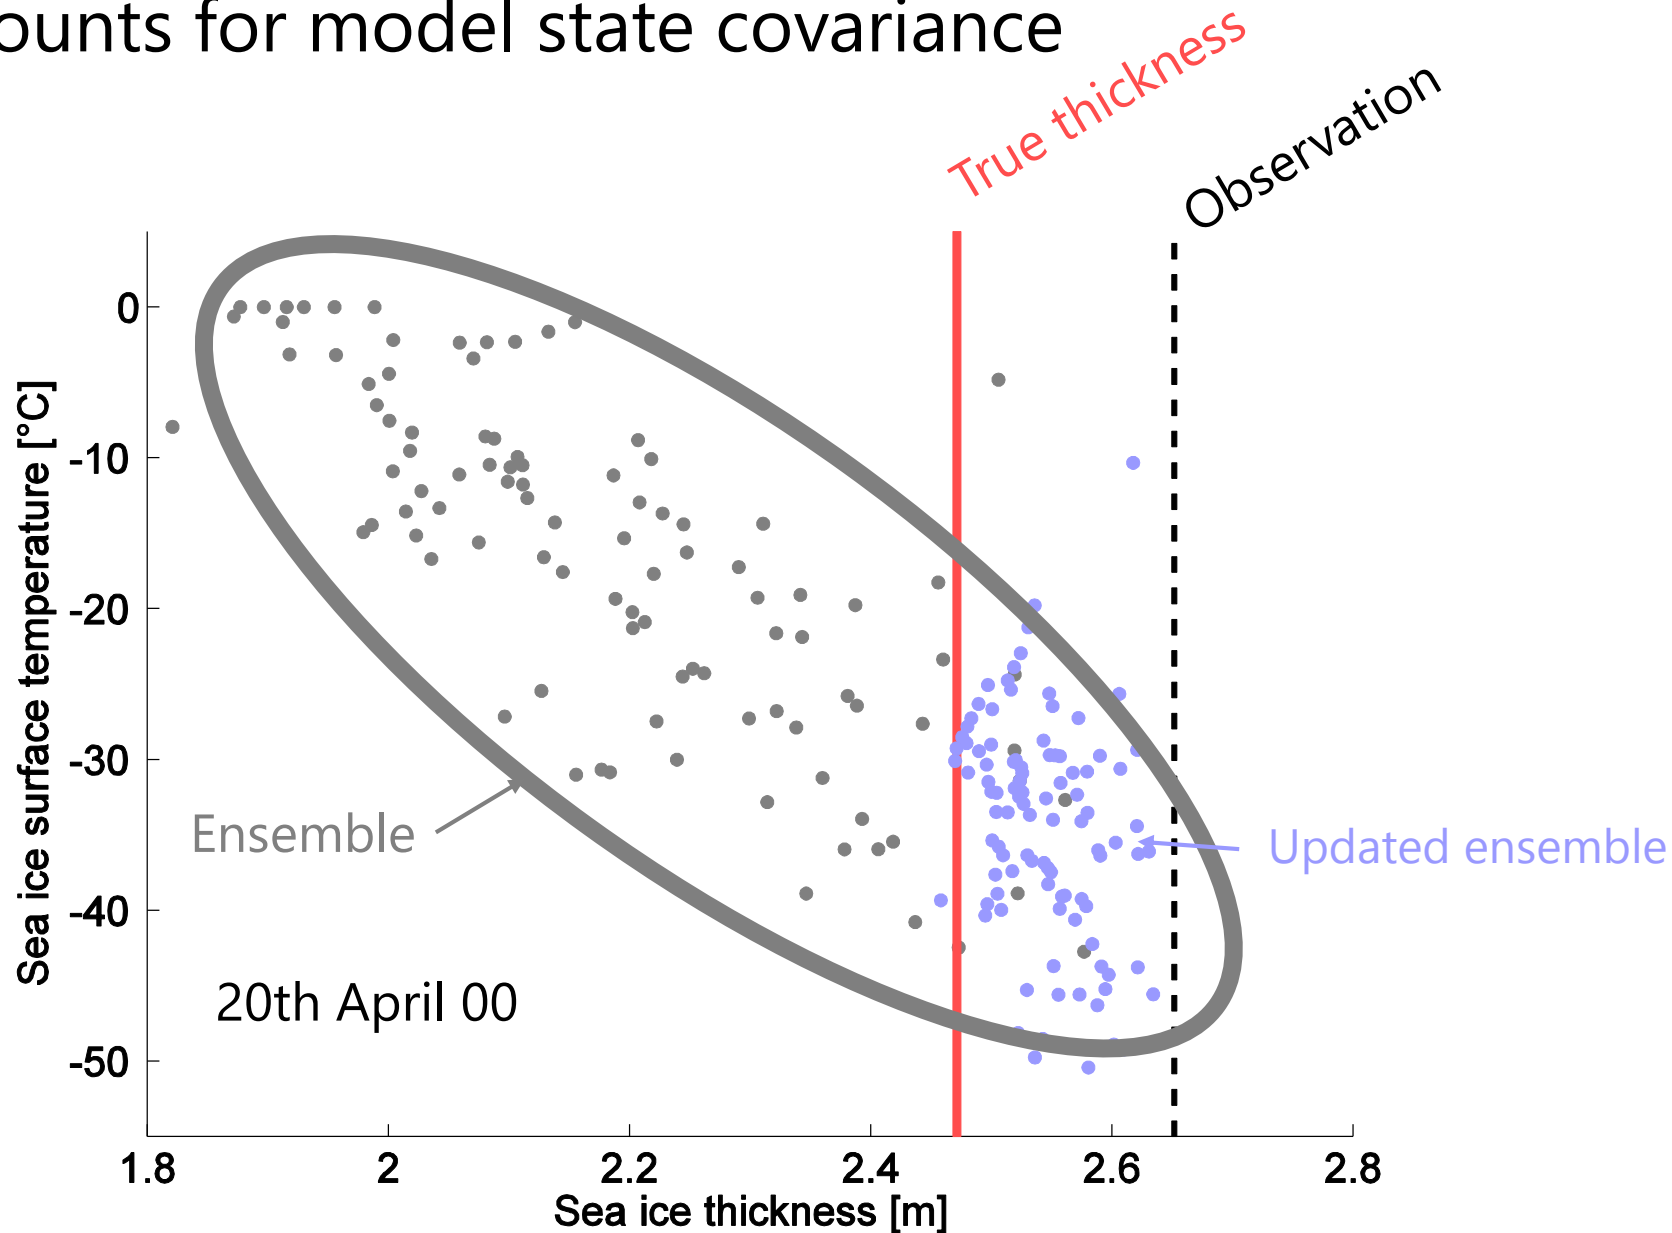

Primitive nudging may bring the system into a non-physical state

Multivariate data assimilation accounts for model state covariance

1. Simple sea ice model

The update of the whole state should be consistent with the model dynamics

2. Comprehensive sea ice model

1. Simple sea ice model

The update of the whole state should be consistent with the model dynamics

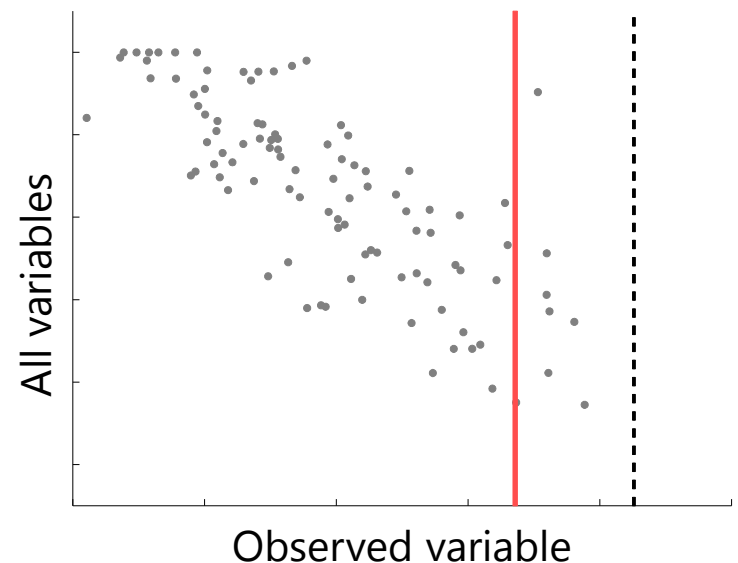

2. Comprehensive sea ice model

Given a comprehensive ocean-sea ice model and observations of total ice concentration,

- How to update concentration in individual categories?
- How to update fields that hold sea ice memory?
- How to keep model dynamics as balanced as possible?

Given a comprehensive ocean-sea ice model and observations of total ice concentration,

- How to update concentration in individual categories?
- How to update fields that hold sea ice memory?
- How to keep model dynamics as balanced as possible?

Covariances are space- and time-dependent!

Correlation (concentration, thickness)
N=25, air surface temperature + winds perturbed

26th March 2000

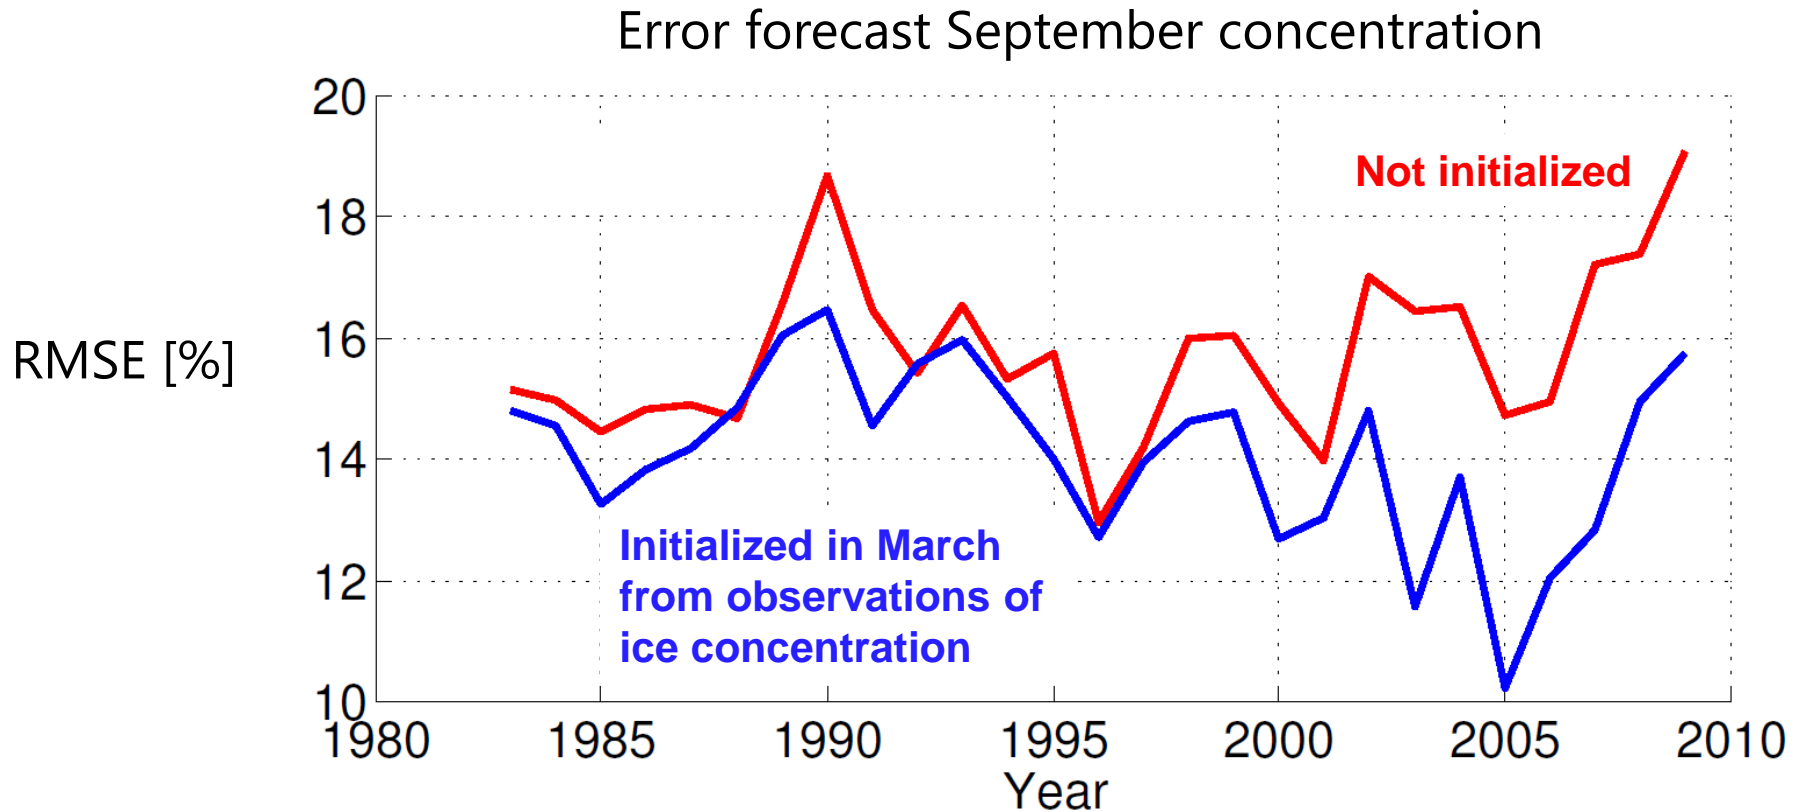

7th September 2000

See also Lisaeter et al., 2003

Initialization from sea ice concentration improves seasonal Arctic predictions

1. Simple sea ice model

The update of the whole state should be consistent with the model dynamics

2. Comprehensive sea ice model

Multivariate data assimilation is promising for seasonal Arctic sea ice prediction

Take home message

In data assimilation for sea ice prediction, the update of the whole sea ice state is

- necessary
- not obvious
- worthwhile

Thank you!
